

# Lecture 3: Networking Concepts

Oct 8

# Administrivia

- Monday: Guest lecture (ME!)
- Wednesday: No lecture, MORE time for project 1

# Recap: The Internet is...

- A federated system
- Of enormous scale
- Dynamic range
- Diversity
- Constantly evolving
- Asynchronous in operation
- Failure prone
- Constrained by what's practical to engineer
- Too complex for theoretical models
- “Working code” needn't mean much
- Performance benchmarks are too narrow

# Today

- What is a network made of?
- How is it shared?
- How do we evaluate a network?
- How is communication organized?

# Performance Metrics

- Delay
- Loss
- Throughput

# Delay

- *How long does it take to send a packet from its source to destination?*

# Delay

- Consists of four components

- *transmission delay*
- *propagation delay*
- *queuing delay*
- *processing delay*

*due to link properties*

*due to traffic mix and  
switch internals*

# A network link

bandwidth

- Link bandwidth
  - *number of bits sent/received per unit time (bits/sec or bps)*
- Propagation delay
  - *time for one bit to move through the link (seconds)*
- Bandwidth-Delay Product (BDP)
  - *number of bits “in flight” at any time*
  - $BDP = \text{bandwidth} \times \text{propagation delay}$

# Examples

- Same city over a slow link:
  - *bandwidth: ~100Mbps*
  - *propagation delay: ~0.1msec*
  - *BDP: 10,000bits (1.25KBytes)*
- Cross-country over fast link:
  - *bandwidth: ~10Gbps*
  - *propagation delay: ~10msec*
  - *BDP:  $10^8$ bits (12.5MBytes)*

# Packet Delay

*Sending 100B packets from A to B?*

1GB file in 100B packets /

*Sending 100B packets from A to B?*

$10^7 \times 100\text{B}$  packets

The last bit in the file  
reaches B at  
 $(10^7 \times 800 \times 1/10^9) + 1/10^3 \text{ s}$   
 $= 8001 \text{ ms}$

The last bit  
reaches B at  
 $(800 \times 1/10^9) + 1/10^3 \text{ s}$   
 $= 1.0008 \text{ ms}$

The last bit  
reaches B at  
 $(800 \times 1/10^6) + 1/10^3 \text{ s}$   
 $= 1.8 \text{ ms}$

# Packet Delay: The “pipe” view

*Sending 100B packets from A to B?*

# Packet Delay: The “pipe” view

*Sending 100B packets from A to B?*

1Mbps, 10ms (BDP=10,000)

1Mbps, **5ms** (BDP=5,000)

**10Mbps**, **1ms** (BDP=10,000)

Packet **200B?**: The “pipe” view  
*Sending 100B packets from A to B?*

# 1. Transmission delay

- How long does it take to push all the bits of a packet into a link?
- Packet size / Link bandwidth
  - *e.g. 1000 bits / 100 Mbits per sec =  $10^{-5}$  sec*

## 2. Propagation delay

- How long does it take to move one bit from one end of a link to the other?
- Link length / Link propagation delay
  - *E.g. 30 kilometers / 3 108 meters per sec = 10-4 sec*

### 3. Queuing delay

- How long does a packet have to sit in a buffer before it is processed?

# Queuing delay: “pipe” view

# Queuing delay: “pipe” view

# Queuing delay: “pipe” view

**Transient Overload**

**Not a rare event!**

# Queuing delay: “pipe” view

# Queuing delay: “pipe” view

# Queuing delay: “pipe” view

# Queuing delay: “pipe” view

# Queuing delay: “pipe” view

**Queues absorb transient bursts but introduce queuing delay**

# Queuing delay: “pipe” view

**What about persistent overload?**  
**Will eventually drop packets (“loss”)**

# Queuing delay

- If arrival rate  $>$  departure rate
  - *approaches infinity (assuming an infinite buffer)*

# Queuing delay

- If arrival rate  $>$  departure rate
  - *approaches infinity (assuming an infinite buffer)*
  - *in practice, finite buffer  $\rightarrow$  loss*
- If arrival rate  $<$  departure rate

**e.g., arrival rate < departure rate**

# Queuing Delay

- If arrival rate  $>$  departure rate
  - *approaches infinity (assuming an infinite buffer)*
  - *in practice, finite buffer  $\rightarrow$  loss*
- If arrival rate  $<$  departure rate
  - *depends on burst size*

# Queuing Delay

- How long does a packet have to sit in a buffer before it is processed?
- Depends on traffic pattern

# Queuing Delay

- How long does a packet have to sit in a buffer before it is processed?
- Depends on traffic pattern
- Characterized with statistical measures
  - *average queuing delay*
  - *average arrival rate*
  - *average departure rate*

# Basic Queuing Theory Terminology

- Arrival process: how packets arrive
  - *Average rate  $A$*
- $W$ : average time packets wait in the queue
  - *$W$  for “waiting time”*
- $L$ : average number of packets waiting in the queue
  - *$L$  for “length of queue”*

# Little's Law (1961)

$$L = A \times W$$

- Compute L: count packets in queue every second
  - *How often does a single packet get counted? W times*
- Why do you care?
  - *Easy to compute L, harder to compute W*

## 4. Processing Delay

- How long does the switch take to process a packet?
- typically assume this is negligible

# Delay

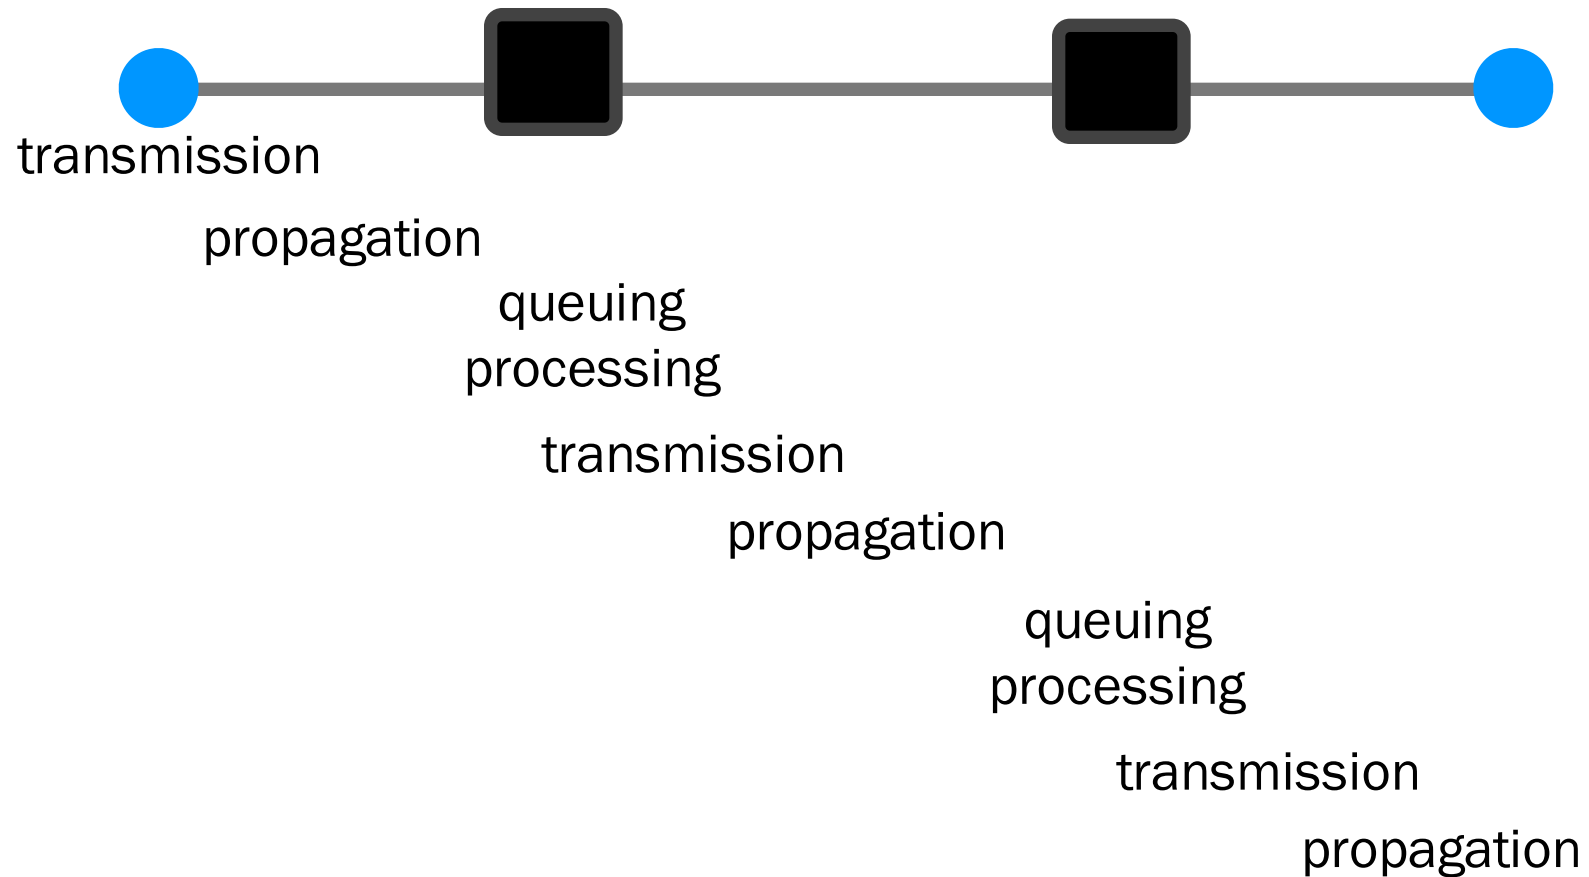

- Consists of four components

- *transmission delay*
- *propagation delay*
- *queuing delay*
- *processing delay*

*due to link properties*

*due to traffic mix and  
switch internals*

# End-to-end Delay

# Loss

- *What fraction of the packets sent to a destination are dropped?*

# Throughput

- *At what rate is the destination receiving data from the source*
  - Data size / transfer time

transmission rate **R** bits/sec

file of size **F** bits

packets of size **L** bits

Transfer time = **F/R** + propagation delay

Average throughput = **R**

transmission rate  $R$

transmission rate  $R' > R$

file of size  $F$  bits

packets of size  $L$  bits

Transfer time =  $F/R$  + propagation delay +  $L/R'$

Average throughput =  $\min \{ R, R' \} = R$

transmission rate  $R$

transmission rate  $R' > R$

file of size  $F$  bits

packets of size  $L$  bits

bottleneck link

Average throughput =  $\min \{ R, R' \} = R$

transmission rate  $R_1$

transmission rate  $R_2$

bottleneck links

transmission rate  $R1$

transmission rate  $R2$

bottleneck link(s)

# Throughput

- At what rate is the destination receiving data from the source?
- Later in the quarter
  - *TCP throughput, application-level throughput, etc.*
  - *throughput vs. “goodput”*

# Plan of attack

- What is a network made of?
- How is it shared?
- How do we evaluate a network?
- How is communication organized?

# Three steps

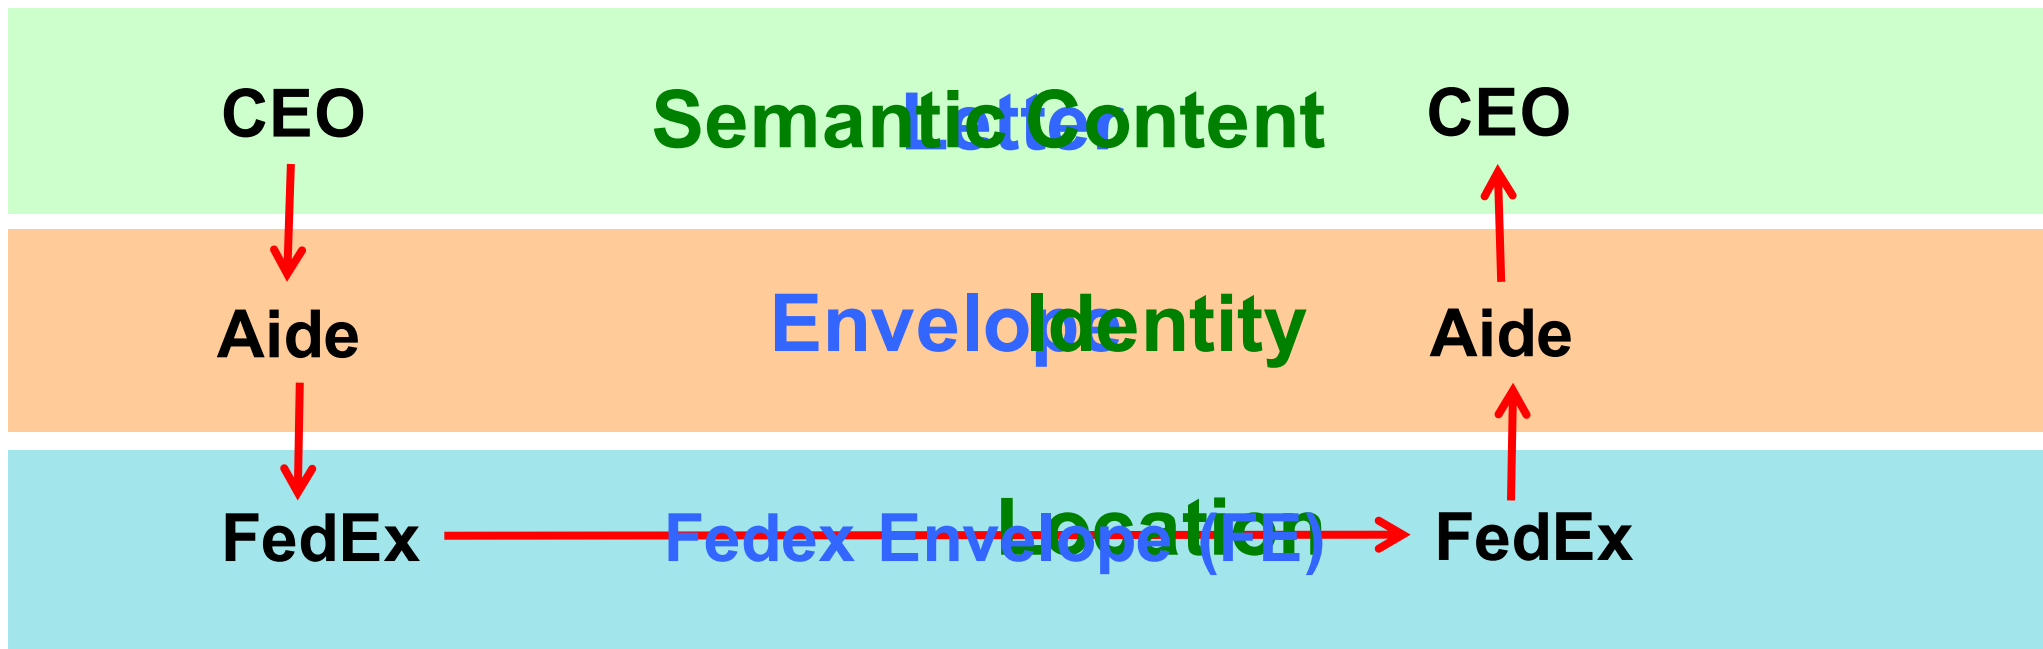

- **Decompose** the problem into tasks
- **Organize** these tasks
- **Assign** tasks to entities (who does what)

# Inspiration...

- CEO A writes letter to CEO B
  - *Folds letter and hands it to administrative aide*
- Aide:
  - *Dear Marissa,* Puts letter in envelope with CEO B's full name
  - *Takes to FedEx*
- FedEx Office
  - *Let's talk merger...* Puts letter in larger envelope
  - *Tim* Puts name and street address on FedEx envelope
  - Puts package on FedEx delivery truck
- FedEx delivers to other company

# The Path of the Letter

- “Peers” in the same layer understand the same things
- No one else needs to
- Lowest level has most packaging

# In the Internet: decomposition

**Applications**

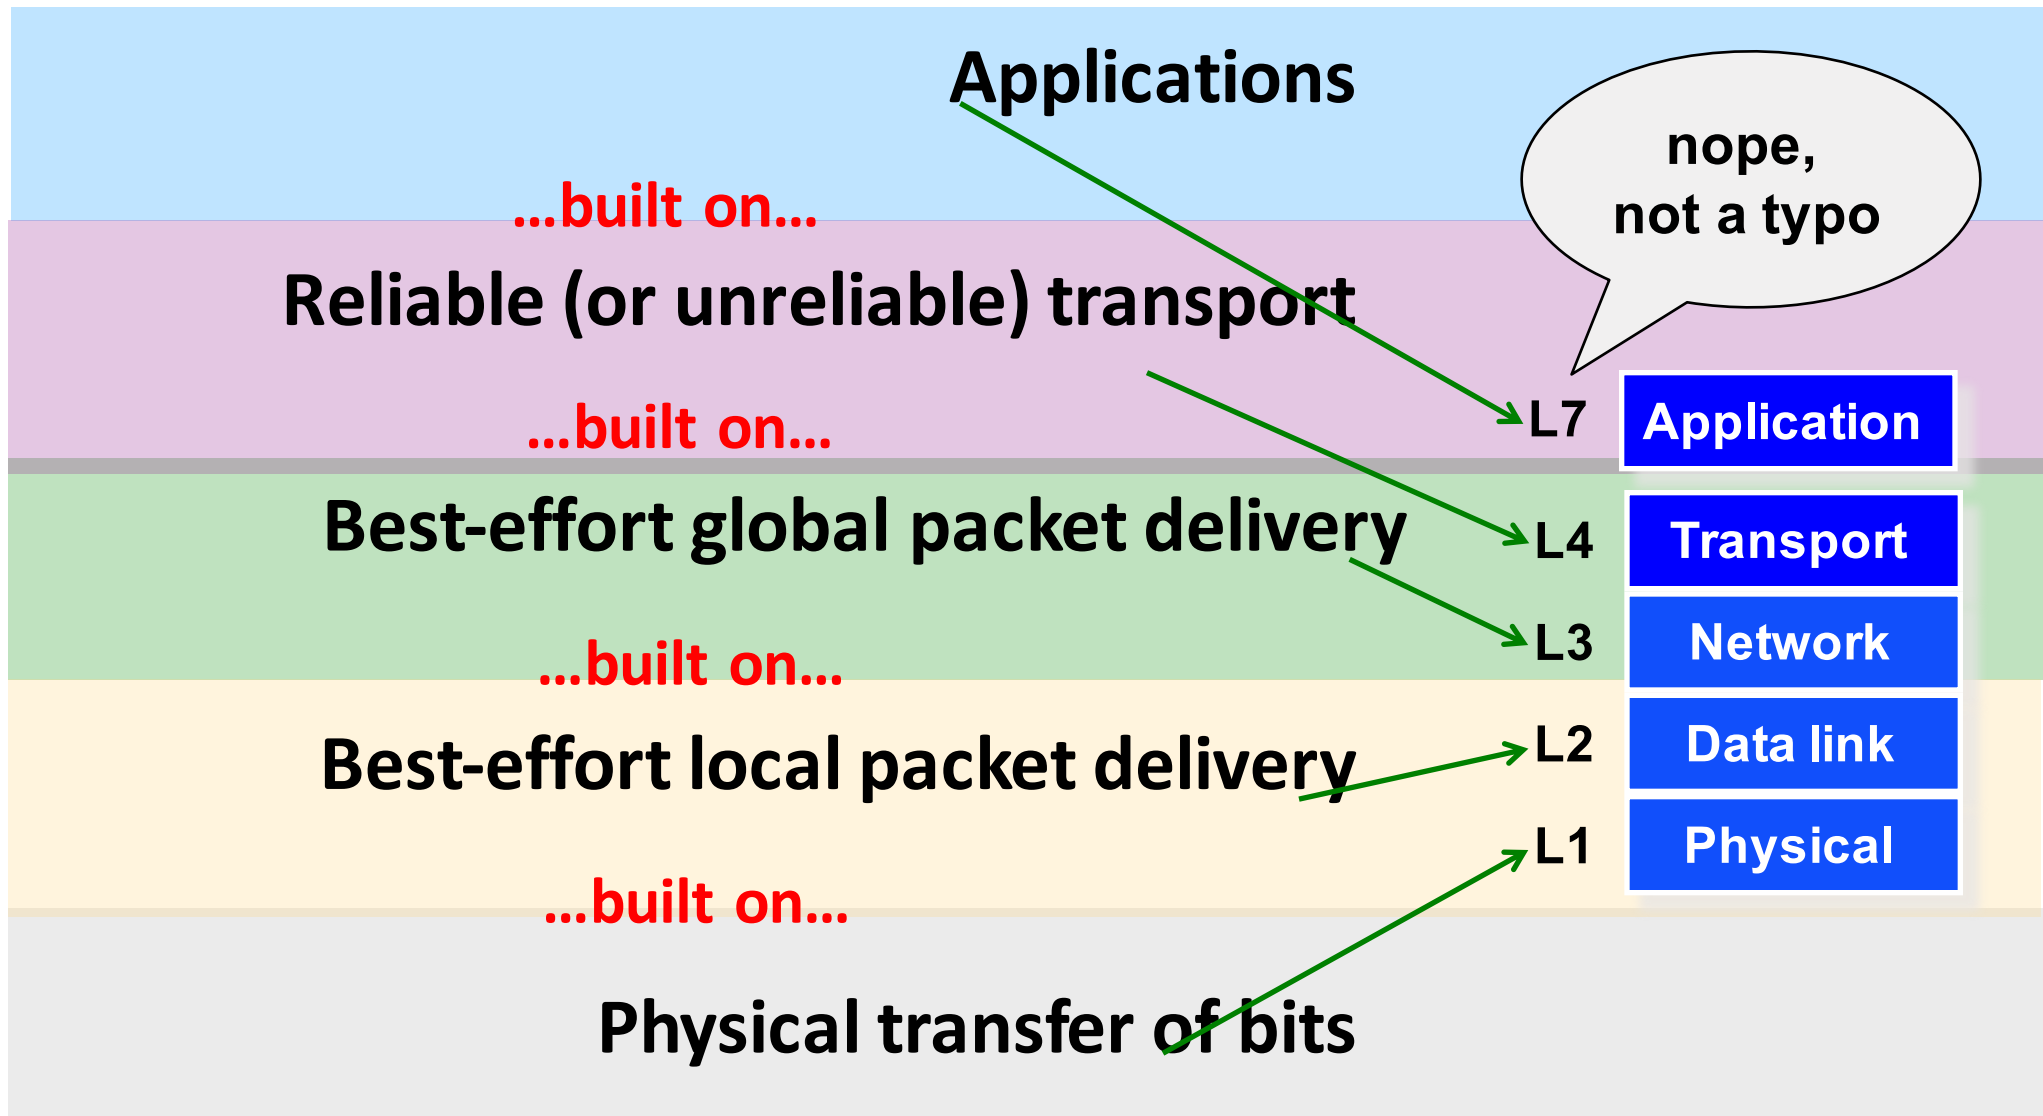

**Reliable (or unreliable) transport**

**Best-effort *global* packet delivery**

**Best-effort local *packet* delivery**

**Physical transfer of bits**

# In the Internet: organization

# In the context of the Internet

Open Systems Interconnect (OSI) model developed by ISO included two additional layers that are often implemented as part of the application
